

(a) The guard was measuring missingness, not information

(b) Both had $|\rho|=1.000$.
Only one hurt to remove.

Why the two differ

fund_cat is a private copy of grp, and grp is shared by 7 domains. Remove it and funding must share one scale with six neighbours -> it loses its own slope.

mob_nlang duplicates target_breadth, which is already a per-domain base column. Nothing to lose.

So: correlation tells you the columns agree. It does not tell you whether removing one costs anything. The pair's SHARING WIDTH does.
